Intermittent claudication

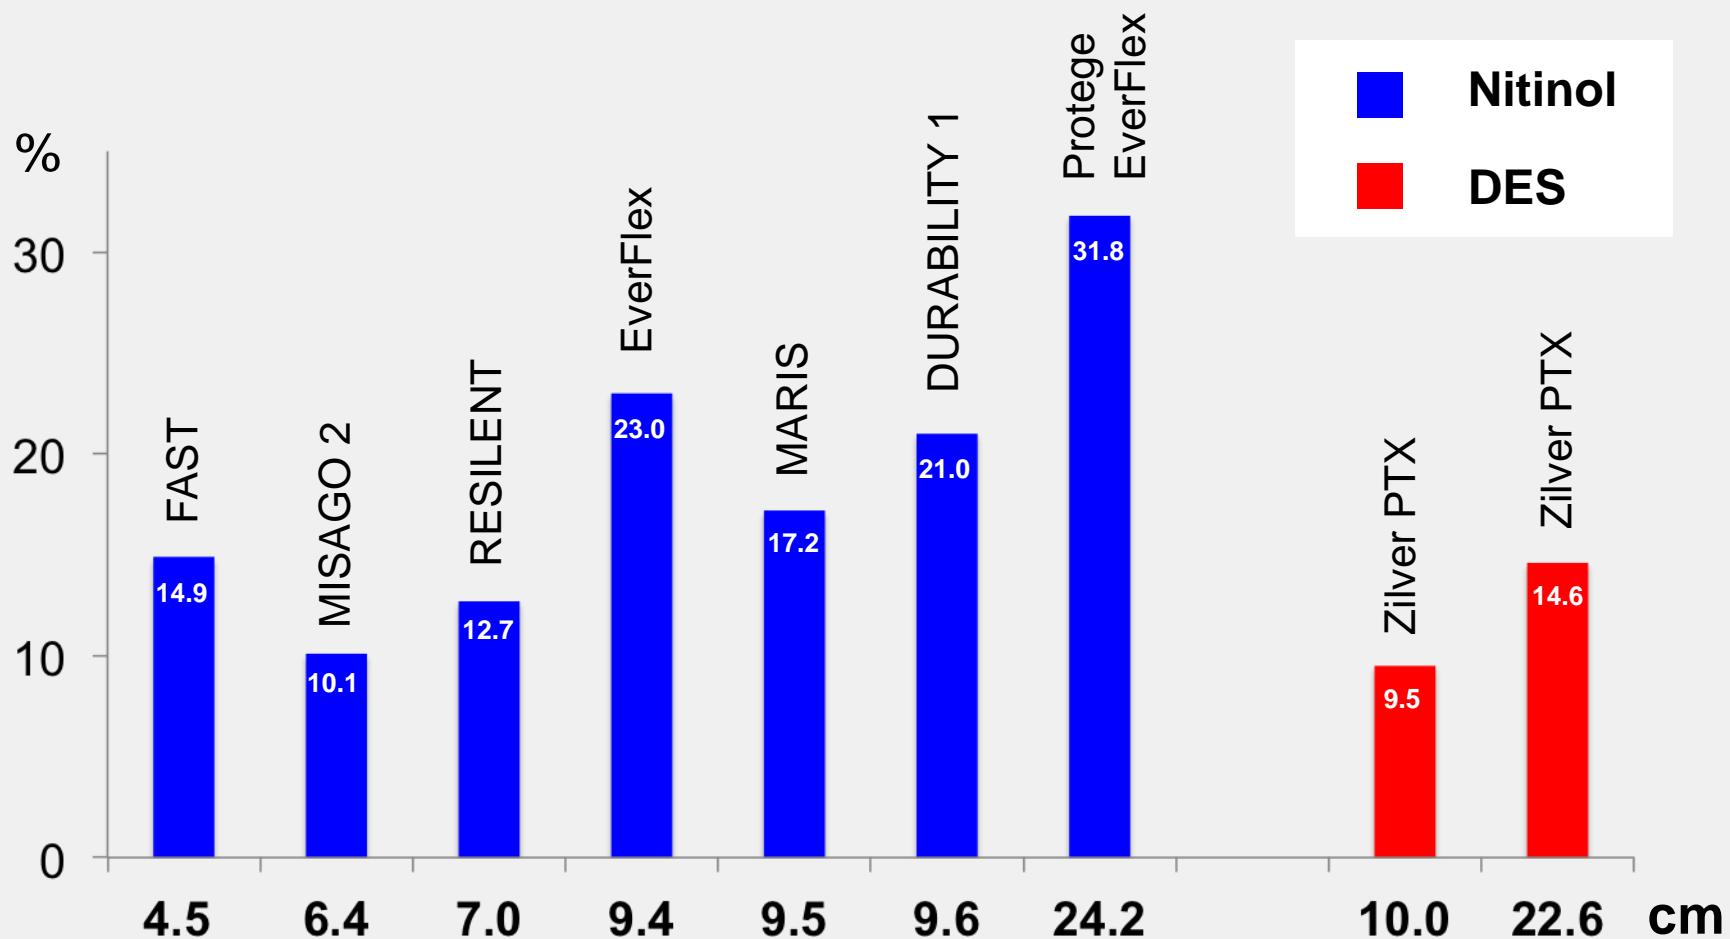

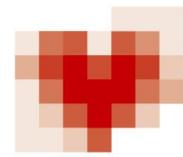

ESC-Guidelines

Endovascular first

Recommendations for revascularization in patients with femoropopliteal lesions

Recommendations	Class ^a	Level ^b	Ref ^c
When revascularization is indicated, an endovascular-first strategy is recommended in all femoropopliteal TASC A–C lesions.	I	C	-
Primary stent implantation should be considered in femoropopliteal TASC B lesions.	IIa	A	285, 286, 291
A primary endovascular approach may also be considered in TASC D lesions in patients with severe comorbidities and the availability of an experienced interventionist.	IIb	C	-

12-month TLR following SFA-stenting

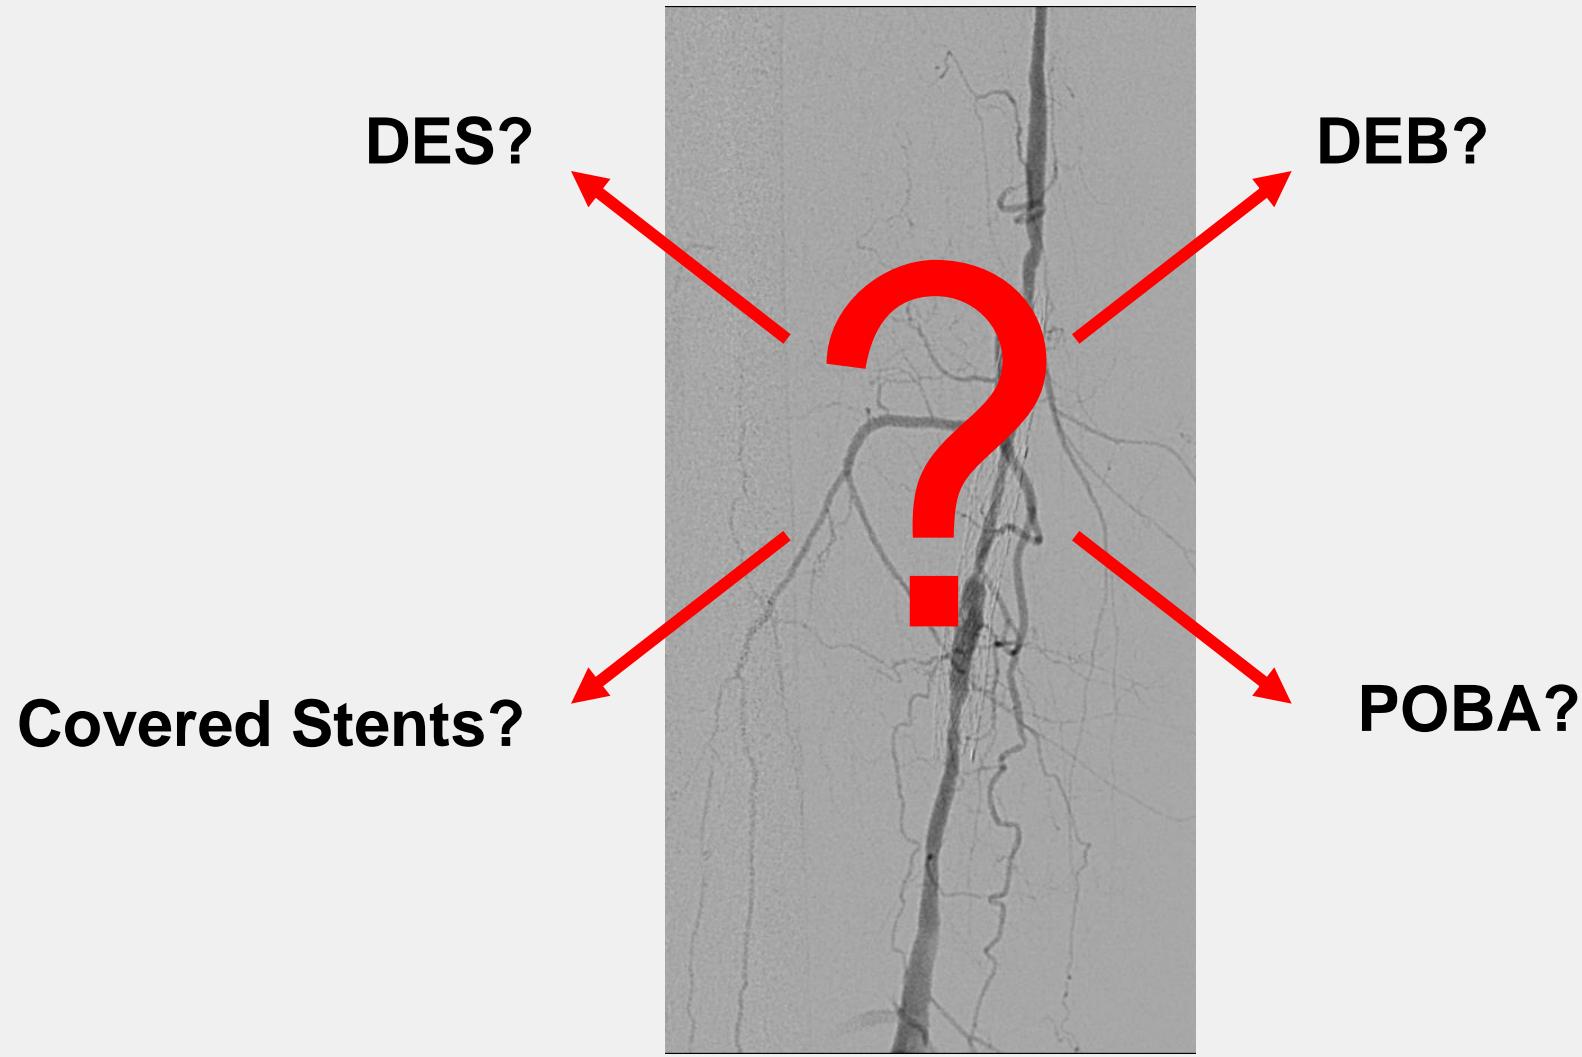

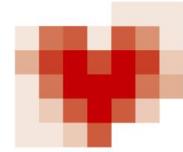

With stenting increasingly performed in the SFA,
an increasing number of patients will require
repeat treatment for **in-stent restenosis**

Drug Eluting Balloon vs. PTA for Superficial Femoral Artery In-Stent Restenosis

Investigator initiated, corelab adjudicated, prospective,
multicenter, randomized trial

Objective: to assess safety and efficacy of PTA with drug-eluting balloon (IN.PACT Admiral, Medtronic) vs. standard PTA for the treatment of symptomatic SFA-ISR

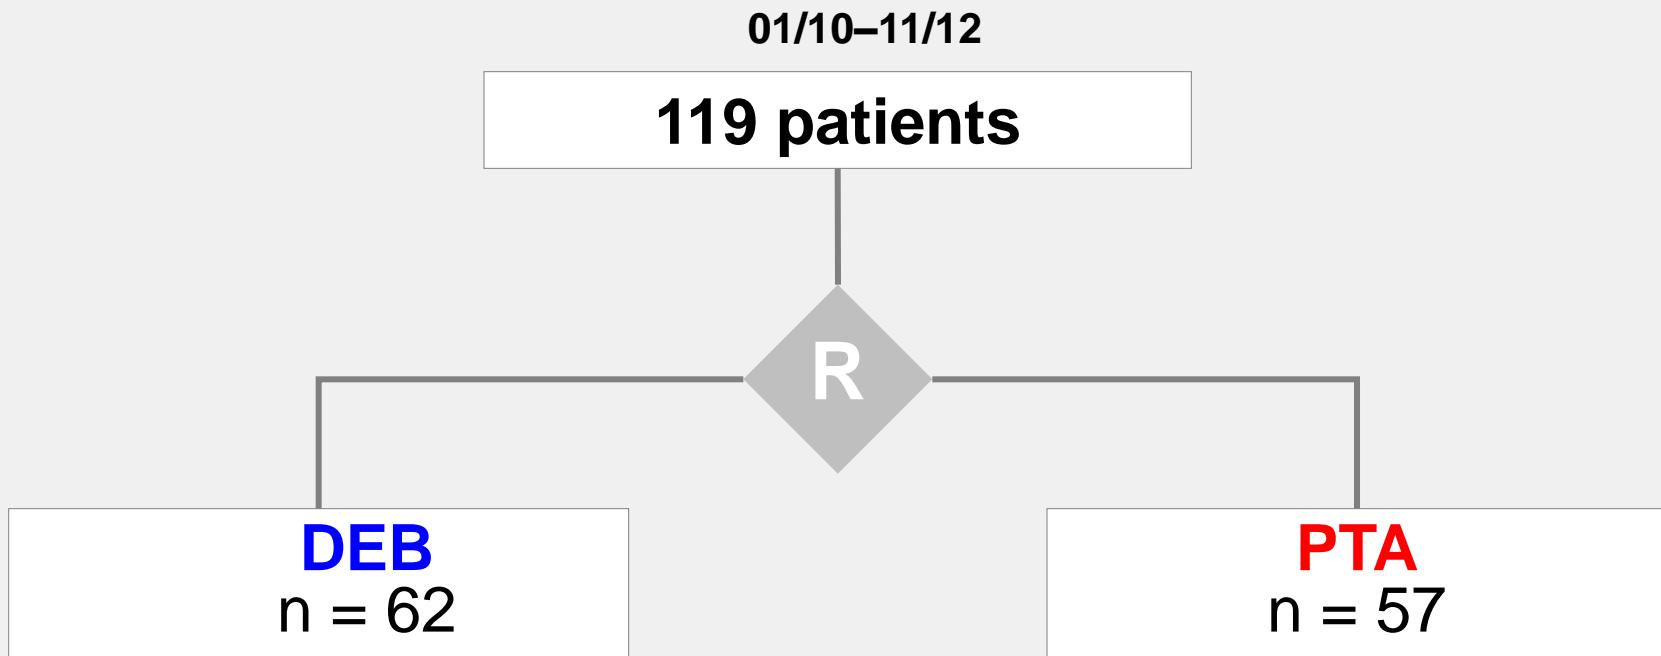

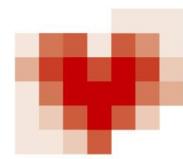

Primary Endpoint: Binary ($\geq 50\%$) restenosis rate at 6 months by duplex ultrasound corelab adjudication (PSVR ≥ 2.4)

DEB vs. PTA in SFA-ISR

FAIR – Trial profile

Summary

- A few small trials show promising results for **covered stents** (GORE VIABAHN) in SFA-ISR. A larger, randomized study is ongoing (GORE VIABAHN vs. POBA, Bosier M, NCT01108861).
- **DES** (Zilver PTX) in SFA-ISR resulted in a similiar 12-month TLR rate compared to DEB and promising 24-month clinical outcomes.
- **DEB** (IN.PACT) in SFA-ISR is associated with less binary restenoses and clinically driven TLR through 6 +12 months than POBA.

Intra stent restenosis: POBA, DEB, DES or covered stent?
